EPIDEMIOLOGIC NOTES AND REPORTS

ASEPTIC MENINGITIS - Eagle Butte, South Dakota

In an outbreak of aseptic meningitis in Eagle Butte, a small community in west-central South Dakota adjacent to a Sioux Indian reservation, between April 1 and May 9, 1967, 18 patients were hospitalized in the USPHS Indian Hospital with illnesses characterized by fever, headache, and stiff neck. Of 12 lumbar punctures performed, 8 revealed CSF leukocytosis. In addition to the 18 hospitalized cases, 101 milder illnesses were uncovered, characterized principally by headache. Fever and stiff neck were infrequent among this group, and in general symptoms lasted three to five days. Of the 114

suspect cases thus far seen, 70 were in grade school students in a dormitory housing 300.

ECHO virus type 4 has been recovered from five patients and may be the predominant causative agent. Epidemiologic and laboratory studies are in progress. (Reported by G.J. Van Heuvelen, M.D., State Health Officer, South Dakota State Department of Health.)

NARCOTICS-ASSOCIATED HEPATITIS - New Jersey

An outbreak of 14 cases of viral hepatitis occurred among a group of 57 known or suspected narcotics addicts in one county of New Jersey between September 1966 and May 1967. Of these, 12 were concentrated during February, March, and April 1967. Fifty-five of the 57 addicts were male; their ages ranged from 17 to 36 years; 49 were between 18 and 24 years old.

Eight of the 14 cases were hospitalized with jaundice; two had a history of jaundice and four the anicteric form of the illness. Figure 1 shows the month of onset of these cases.

All of the 14 patients were known to have shared injection equipment with at least one person who either had been ill with hepatitis or subsequently developed the disease. There was such extensive sharing among different addicts and repeated use by individual addicts that valid incubation periods could not be determined.

A single serum specimen was collected during the week of April 24 from 55 of the 57 addicts in the group. Serum glutamic pyruvic transaminase (SGPT) values are shown in Table 1. Forty-three had no history of illness or

jaundice in the preceding 6 months, but 29 (67 percent) had SGPT values above 40, well above normal levels. Moreover, 12 values were above 100.

Table 2 examines the serum transaminase results among the 43 non-ill addicts according to the history of having shared narcotics equipment with one or more of the 14 known cases. Twenty-two had shared equipment with at least one of the addicts with hepatitis, and 21 did not admit such sharing. Of the former group, 19 (90 percent) had SGPT values above 40. Among the 21 in the latter group, only 10 (48 percent) had values above 40. Thus, the sharing of injection equipment with an addict who had hepatitis was associated with a greater frequency of elevated SGPT values.

(Reported by W.J. Dougherty, M.D., Director, Division of Preventable Diseases, New Jersey State Department of Health; and an EIS Officer.)

Table 1
SGPT Values Among 57 Addicts

SGPT Values	Addict Group

Total	14	29	43

TYPHOID FEVER - Louisiana

A familial outbreak of typhoid fever caused by *Salmonella typhi*, phage type B₂, occurred in northwestern Louisiana in December 1966 and January 1967. Eight of the 14 persons identified as being infected had clinical symptoms; 6 were asymptomatic. The source of infection was not determined.

The index case was reported from a rural section of Red River Parish, 30 miles south of Shreveport. The

patient began having sweats, chills, and fever on December 5. He continued to attend school until December 8, when he first consulted a physician. His temperature was then 104°F. The physician gave him penicillin and streptomycin for four days, but his condition did not improve. He stayed at home in bed until December 18, when he was advised to go to a Shreveport hospital. After spending the

Pneumonia and Influenza, All Ages----- 10,391
All Causes, Under 1 Year of Age----- 13,459

*Estimate - based on average percent of divisional total.

TYPHOID FEVER - Louisiana

(Continued from page 170)

night with relatives in Shreveport, he entered the hospital, where he was cared for by a relative and his parents until discharged on January 5. He again spent the night with his Shreveport relatives, went home, and four days later returned with his mother, father, two siblings, and an aunt to visit the relatives in Shreveport.

Between January 10 and 23, seven members of the Shreveport family had symptoms of typhoid fever. Stool samples from the patient and 13 of his family or contacts were cultured and grew *S. typhi*, phage type B₂, although only eight of these persons had clinical signs of illness.

Epidemiologic investigation revealed such insanitary environmental conditions in both the index patient's home and his relatives' home as to provide ample opportunity for spread of infection. Food and activity histories of the index patient for the month prior to onset of illness suggested no probable source of infection.

Two cases of typhoid fever in persons who were excreting the same phage type and who had approximately the same onset dates as the index case were investigated in a neighboring parish. No link could be established between the 14 familial infections and these other two cases. Approximately 40 family contacts were immunized. Numbers of stool specimens from family members and contacts have contained no *S. typhi* organisms.

(Reported by John A. Trautman, M.D., Chief, Section of Epidemiology, Division of Preventive Medicine, Louisiana State Board of Health; and an EIS Officer.)
